

# Choosing AI techniques

a Fundamental Topic of Software Engineering for  
Artificial Intelligence

# Outline

---

1. Making intelligence
2. Machine learning fundamentals
3. Machine learning approaches
4. Choosing the right approach
5. Common solution for common problems

1. Making intelligence
  - a. What is Intelligence?
  - b. Representing Intelligence?
  - c. Creating Intelligence?
2. Machine learning fundamentals
3. Machine learning approaches
4. Choosing the right approach
5. Common solution for common problems

# Making Intelligence

---

- intelligence = decision making component of a system
- maps context to a prediction
- context must be implemented in the intelligence runtime
- intelligence should be available to the creator
  - intelligent systems work best if the data comes from users

# Making Intelligence

- intelligence can represent as:
  - program that tests multiple conditions
  - hand-labelling specific context and store it in lookup table
  - building models with ML
  - combination of the above
- criteria for a good representation
  - compact: can be loaded into the intelligence runtime
  - easy to load and execute in a runtime
  - safe for frequent updates, no system crashing bugs

# Making Intelligence

---

- intelligence creating process is iterative
  1. Understanding the environment
  2. Defining success
  3. Getting data
  4. Getting ready to evaluate
  5. Trying simple heuristics
  6. Trying simple machine learning
  7. Assessing and iterating until you succeed

1. Making intelligence
2. Machine learning fundamentals
  - a. Feature Engineering
  - b. Model Complexity
3. Machine learning approaches
4. Choosing the right approach
5. Common solution for common problems

Factors (among others) that intelligence creators must control :

- Feature Engineering
- Model structure complexity
- Model search complexity:
- Data Size

- Feature Engineering:
  - Converting data to useful form.
  - Helping the model use the data.
  - Normalizing feature values.
  - Exposing hidden information.
  - Expanding the context.
  - Eliminating misleading things.

## Structure- & Search complexity:

- complex models to solve hard, big, open-ended problems.
- more complexity → higher chance the model misunderstands the concept.
  - It might underfit the concept, in that its understanding of the concept might be too simple.
  - It might overfit the concept, in that its understanding of the concept is wrong; it happens to work in some contexts, but it just isn't right.

# Outline

---

1. Making intelligence
2. Machine learning fundamentals
3. **Machine learning approaches**
4. Choosing the right approach
5. Common solution for common problems

# Machine learning approaches

---

- Start with a simple model.
- Try slightly refined versions of the model (informed by the training data).
- Check to see if the refined versions are better (using the training data).
- And iterate (roughly) until their search procedure can't find better models.

# Machine learning approaches

---

- Supervised machine learning
  - models relationship between target prediction and input features (labeled data)
- Unsupervised machine learning
  - explores input without an explicit output (pattern detection & descriptive modeling)
- Semi-supervised learning
  - part of the data is labeled, model learns the structures to organize the data
- Reinforcement learning :
  - learning a task by trying to maximize the rewards in iterative fashion

1. Making intelligence
2. Machine learning fundamentals
3. Machine learning approaches
4. **Choosing the right approach**
  - a. Set the parameters
  - b. Choose the technique
5. Common solution for common problems

# Choosing the right approach

---

1. Know your problem
  - a. is it solvable?
  - b. define if the problem is hard
  - c. define success scenarios
  - d. Software requirements (functional-, non-functional- and domain specific requirements)
2. Know your data
  - a. Look at summary statistics and visualizations
  - b. Visualize the data
  - c. Look for main features

# Choosing the right approach

---

3. Process the data
  - a. preprocessing
  - b. clean the data
  - c. profile the data
  - d. Aggregate if needed
4. Transform the data: data  $\rightarrow$  features
  - a. weight the important features
  - b. eliminate misleading data samples
  - c. normalize the data

# Choosing the right approach

---

Tweak the complexity parameters:

- how fast should the training be?
- how fast should the prediction be?
- how accurate should the module predict?
- how flexible should the model be?
- how much memory /computing power is available?
- how much training data is available?
- how many useful features are available in the data?

# Choosing the right approach

## tradeoffs

- **accuracy vs decision speed**
- **simple vs flexible**
- **training set size vs required memory**
- **training set size vs training time**
- **variance vs bias**
- **scalability vs # of Features**
- **interpretability vs accuracy**
- **# of Features vs prediction time**
- ...

1. Making intelligence
2. Machine learning fundamentals
3. Machine learning approaches
4. **Choosing the right approach**
  - a. Set the parameters
  - b. **Choose the technique**
5. Common solution for common problems

# Choosing the right approach

---

- Categorize the problem by input
  - a. labeled data → supervised learning
  - b. unlabeled data, want to find structure → unsupervised learning
  - c. labeling all data too expensive, labels serve as boundary → semi-supervised
  - d. optimize a function by interacting with environment → reinforcement learning

# Choosing the right approach

---

- Categorize problem by output
  - a. output is a pattern → data correlation
  - b. output is a number → regression
  - c. output is a class → classification
  - d. output is a set of groups → clustering
  - e. output is an anomaly → anomaly detection

# Choosing the right approach

- Find the right algorithm:
  1. define problem
  2. choose the right set of data
  3. set complexity parameters, in regards to trade-offs
  4. define suitable candidates (as we will see in example in the next slides)
  5. implement and analyze in regards to one another
    - ◉ if we didn't achieve at least one success scenario go back to 2 (lack of data) or 3 (tweak complexity parameters)
  6. choose best performing one(s)
- many different algorithms for different problems
- no one-size-fits-all approach

1. Making intelligence
2. Machine learning fundamentals
3. Machine learning approaches
4. Choosing the right approach
5. Common solution for common problems
  - a. Supervised algorithms
  - b. Unsupervised algorithms
  - c. Reinforcement learning

# Supervised machine learning

Algorithm	How does it work?	Exemplary use	Advantages	Disadvantages
Linear Regression	<ul style="list-style-type: none"><li>- approximate input using polynomial regression</li><li>- continuous output</li></ul>	understand product sales drivers. optimize price points.	<ul style="list-style-type: none"><li>- fast to implement and train</li><li>- prone to overfit, but solvable with L1 or L2 reduction</li><li>- performs well on linearly separable data</li></ul>	<ul style="list-style-type: none"><li>- can suffer from outliers</li><li>- problematic with nonlinear functions</li></ul>
Logistic Regression	<ul style="list-style-type: none"><li>- approximate input using logistic regression</li><li>- discrete output</li></ul>	Classify customers based on how likely they are to repay the loan.	<ul style="list-style-type: none"><li>- fast to implement and train</li><li>- transparent</li><li>- updates weight gradually over examples → no need to retrain</li><li>- gives probabilistic output</li></ul>	<ul style="list-style-type: none"><li>- needs a lot of data(for supervised)</li><li>- assumption of linearity in the logit</li><li>- suffers from outliers</li></ul>
Naive Bayes	<ul style="list-style-type: none"><li>- build a classifier</li><li>- Bayes Assumption: value is independent of values of other features</li></ul>	a framework for hiring new employees	<ul style="list-style-type: none"><li>- easy and fast to train and implement</li><li>- memory efficient</li><li>- easy to understand</li><li>- takes prior knowledge into account</li></ul>	<ul style="list-style-type: none"><li>- strong feature independence</li><li>- fails classifying rare occurrences</li><li>- irrelevant features</li></ul>

# Supervised machine learning

Algorithm	How does it work?	Exemplary use	Advantages	Disadvantages
Random Forest	<ul style="list-style-type: none"><li>- ensemble method for classification, regression, ao.</li><li>- constructs multiple decision trees in runtime</li></ul>	Object detection	<ul style="list-style-type: none"><li>- can work in parallel</li><li>- no need to tweak parameters</li><li>- can handle missing values</li><li>- seldom overfits</li><li>- easy to use</li></ul>	<ul style="list-style-type: none"><li>- biased in multiclass problems</li><li>- difficult to interpret</li><li>- weaker on regression when dealing with extrema</li></ul>
SVN	<ul style="list-style-type: none"><li>- used for regression and classification</li><li>- find hyperplane in a N-dimensional space with maximum margin</li></ul>	Predict how likely someone is to click on an online ad	<ul style="list-style-type: none"><li>- relatively memory efficient</li><li>- good at approximating complex functions</li><li>- works well for clear separation margin between classes</li></ul>	<ul style="list-style-type: none"><li>- difficult to interpret</li><li>- not suited for large datasets</li><li>- suffers from noise, overlapping classes</li></ul>

# Unsupervised machine learning

Algorithm	How does it work?	Exemplary use	Advantages	Disadvantages
K-means clustering	<ul style="list-style-type: none"><li>- group similar data points and discover patterns</li><li>- look at k clusters</li><li>- starts with random centroid and optimizes from it</li></ul>	Computer vision  Spell checking problems	<ul style="list-style-type: none"><li>- efficient <math>O(K*n*d)</math></li><li>- tight clusters</li><li>- easy to implement</li></ul>	<ul style="list-style-type: none"><li>- order of data and seed impact result</li><li>- scale sensitive</li><li>- difficult to predict number of clusters</li></ul>
Hierarchical clustering	<ul style="list-style-type: none"><li>- Agglomerative: compute proximity matrix → each point is a cluster → merge two closest clusters → repeat</li><li>- Divisive: opposite, rarely used</li></ul>	Charting Evolution through Phylogenetic Trees  Clustering politicians by Twitter posts	<ul style="list-style-type: none"><li>- easy to implement</li><li>- hierarchical → easy to decide on number of clusters (dendrogram)</li><li>- flexible</li></ul>	<ul style="list-style-type: none"><li>- inefficient <math>O((n^3)*d)</math></li><li>- very sensitive to outliers</li><li>- can't handle big data</li><li>- can't step back during procedure</li></ul>

# Unsupervised machine learning

Algorithm	How does it work?	Exemplary use	Advantages	Disadvantages
SVD	<ul style="list-style-type: none"><li>- factorizes a matrix to 3 matrices</li><li>- reduce R rank matrix to K rank matrix</li></ul>	Recommender systems	<ul style="list-style-type: none"><li>- restructure data to:</li><li>- reduce overfitting</li><li>- improve performance</li><li>- remove correlated features</li></ul>	<ul style="list-style-type: none"><li>- difficult to interpret</li><li>- information loss</li><li>- difficult to understand restructuring</li></ul>
Gaussian mixture model	<ul style="list-style-type: none"><li>- cluster according to a different Gaussian distribution</li><li>- each data point approximated using a gaussian distribution using EM</li></ul>	feature extraction from speech data  object tracking in video data	<ul style="list-style-type: none"><li>- fastest algorithm for learning mixture models</li><li>- maximizes only the likelihood, it will not bias the means towards zero</li></ul>	<ul style="list-style-type: none"><li>- will always use all the components it has access to</li></ul>

# Reinforcement learning

Algorithm	How does it work?	Exemplary use	Advantages	Disadvantages
Dynamic Programming	<ul style="list-style-type: none"> <li>- compute each value in a state by using values of surrounding states</li> <li>- once done move to next state</li> <li>- repeat until changes are less than defined threshold</li> </ul>	<p>Optimize trading strategy for an options-trading portfolio</p> <p>Stock and pick inventory using robots</p>	<ul style="list-style-type: none"> <li>- efficient, finds policy in polynomial time</li> <li>- guaranteed to find an optimal policy</li> </ul>	<ul style="list-style-type: none"> <li>- not suitable for large problems</li> <li>- requires knowledge of transition probability matrix</li> </ul>
Temporal Difference (TD)	<ul style="list-style-type: none"> <li>- choose an action A on State S with X% according to policy and Y% random</li> <li>- calculate S' and reward</li> <li>- compute average at V(s)</li> <li>- update S to S'</li> </ul>	<p>Optimize the driving behavior of self-driving cars</p> <p>Optimize pricing in real time for an online auction of a product with limited supply</p>	<ul style="list-style-type: none"> <li>- does not need to know the transition probability matrix</li> <li>- due to incremental updates no need to wait for the end of an episode</li> </ul>	<ul style="list-style-type: none"> <li>- problem with local minima</li> <li>- faster but unstable</li> <li>- might converge to wrong solution if model starts wrong</li> </ul>
Neural Networks	<ul style="list-style-type: none"> <li>- simulates human brain</li> <li>- takes in the weight of connections between neurons</li> <li>- trains weights based on automatically generated character. of processed samples</li> </ul>		<ul style="list-style-type: none"> <li>- Can approximate any nonlinear function</li> <li>- robust to outliers</li> <li>- can work with only support vectors</li> </ul>	<ul style="list-style-type: none"> <li>- easy to overfit</li> <li>- difficult to setup and tune</li> <li>- difficult to interpret</li> <li>- very resource and memory intensive</li> </ul>
